ABSTRACT

Purpose: We used serologic screening of a cDNA expression library of human testis to identify novel cancer/testis antigens that elicit both humoral and cellular immune responses in cancer patients.

Experimental Design and Results: We identified a novel gene designated KM-HN-1, the expression of which is testis-specific among normal tissues; it contains coiled coil domains and a leucine zipper motif and encodes a putative protein consisting of 833 amino acids. KM-HN-1 expression was observed in various cancer tissues and cancer cell lines at both mRNA and protein levels. Immunofluorescence staining of an esophageal cancer cell line revealed that KM-HN-1 protein was present exclusively in the nucleus during mitosis. Recombinant KM-HN-1 protein, and used for ELISA to quantitate levels of IgG antibody specific to KM-HN-1. Higher levels of IgG antibodies specific to KM-HN-1 were detected in many types and numbers of cancer patients but not in healthy donors. The CTL lines specific to KM-HN-1, generated from HLA-A*2402-positive healthy donors and cancer patients, killed human leukocyte antigen (HLA)-A24-positive cancer cells expressing KM-HN-1 but not cell lines that did not express either KM-HN-1 or HLA-A24.

Conclusions: We identified a novel cancer/testis antigen, KM-HN-1, which elicited humoral immune responses in patients with various types of cancer. Furthermore, KM-HN-1-specific CTLs could be generated from both healthy donors and cancer patients, which indicated that KM-HN-1 can be a candidate for an ideal target for cancer immunotherapy.

INTRODUCTION

Identification of tumor antigens capable of inducing an anticancer immune response in cancer patients and development of immunogenic cancer vaccines targeting these antigens represent formidable tasks confronting tumor immunologists (1). In the early 1990s, van der Bruggen et al. (2) and Traversari et al. (3) reported the first successful cloning of a human tumor antigen, termed melanoma antigen-1 or MAGE-1 (subsequently renamed MAGE-A1), that elicited a spontaneous CTL response in an autologous melanoma patient. Subsequent analysis of normal tissues showed that MAGE-1 is expressed exclusively in normal testis. The tumor expression of MAGE-1, however, was not restricted to melanoma, rather it was also expressed in a remarkable proportion of various cancer cells (4). The testis is an immune privileged organ because spermatogenic cells do not express human leukocyte antigen (HLA) class I and II molecules at the cell surface (5). Concomitantly, the testis has a so-called blood–testis barrier in the seminiferous tubuli generated by Sertoli cells. The ectopic expression of cancer/testis (CT) antigens may thus lead to an autologous cellular and/or humoral immune response (6). Recognizing these striking features, L. J. Old (7) proposed the term CT antigens to encompass this heterogeneous group of antigens, and a CT nomenclature system was also proposed. CT antigens are thought to be an ideal target of cancer immunotherapy. Twenty CT antigen genes or gene families have been identified to date, but coordinated humoral and cellular immune responses have been reported for only a few CT antigens, including MAGE-A1, MAGE-A3, and NY-ESO-1 (6, 8).

The screening of tumor-derived expression libraries for antigens detected by high-titer IgG antibodies from sera of patients with cancer by serological analysis of recombinant tumor cDNA expression libraries with autologous serum (SEREX; serologic identification of antigens by recombinant expression cloning) allows for a systematic search of antigens of immunogenicity in cancer patients. The discovery of immunogenic cancer vaccines targeting these antigens represents a major advance in the field of cancer immunotherapeutic vaccine development. In the late 1990s, van der Bruggen et al. (11) and Brichard et al. (12) identified tyrosinase (10), two antigens originally cloned as SSX tumors in patients with melanoma (13). The cost of publication of this article was defrayed in part by the payment of page charges. This article must therefore be hereby marked advertisement in accordance with 18 U.S.C. Section 1734 solely to indicate this fact.

Identification of a Novel CT Antigen, KM-HN-1

The fact that all CT antigens are also expressed at high levels in testis prompted us to do serologic screening of a testis cDNA expression library enriched for specific transcripts instead of a cDNA library derived from tumor cells. This approach led to identification of several more CT antigens (13). Herein, we report the expression pattern of, and humoral and cellular immune response to, KM-HN-1, a novel CT antigen that we identified with this approach.

MATERIALS AND METHODS

Patients, Tumor Tissues, and Cell Lines. Sera and tumor tissues were obtained during routine diagnostic procedures after obtaining a formal agreement signed by the patients. COS-7 and HSC-4 cells were used for the transfection. The human B lymphoblastoid cell line C1R, expressing a trace amount of HLA class I molecule and C1R-a2402 [a HLA-A*2402 transfectant of C1R cells (14)] were used for peptide-pulse experiments. The other cell lines used in this study were as follows: lung carcinoma (PC-9), esophageal carcinomas (TE3, TE9, TE11, and TE13), and head and neck carcinomas (HSC-4 and HSQ-89). The origins and HLA genotypes of these cell lines have been described elsewhere (15–17).

Cloning and Production of Recombinant Protein of KM-HN-1. Immunologic screening was done as described previously (18). Briefly, cDNA libraries from cell lines of squamous cell carcinoma of head and neck (SCCHN) and a normal testicle tissue were screened with sera from six alloge- ric SCCHN patients. A total of 25 positive clones belonging to 19 different genes, including MAGE-A4 and NY-LU-5, were identified, and details of these genes were described elsewhere (18). Among these clones, a novel gene, KM-HN-1, was expressed only in testis among normal tissues but was expressed in several cancer tissues. So we further investigated KM-HN-1, its features and immunogenicity.

Reverse transcription-PCR (RT-PCR) analysis of normal and cancer tissue was done as described previously (18). Briefly, 1 μg of total RNA was isolated from each sample and converted into cDNA in 20 μL of reaction buffer. PCR was done for 30 cycles for quantification of KM-HN-1 mRNA and for 25 cycles for quantification of β-actin mRNA. KM-HN-1 PCR primer sequences were: sense 5'-CCATCCCCAGATACATTCCGGAGGAC-3' and antisense 5'-GGTCGAGGAAGGACAGTGTTG-3'. RT-PCR was done in at least two independent experiments. Quantitative RT-PCR was carried out in a Roche Lightcycler (Roche Diagnostics, Lewes, United Kingdom) and was quantified by measuring SYBR green. PCR was done with the DNA Master SYBR green PCR reaction mix that contains Taq polymerase, dNTP mix (with dUTP instead of dTTP; Roche), 3 mmol/L MgCl2 with a 0.5 μmol/L concentration of each primer, and either 1 μL of cDNA or 1 μL of water in a total volume of 20 μL. The PCR cycles were 95°C for 10 minutes, followed by 45 cycles of 95°C for 1 second, 68°C for 1 second, and 72°C for 10 seconds. KM-HN-1 PCR primer sequences were as follows: sense 5'-CCATCCCCAGATACATTCCGGAGGAC-3' and antisense 5'-CTGATTCTCCGACTGTCCATGCTG-3'. Quantification was achieved by comparison with an internal standard curve containing 10-fold dilutions of testis cDNA probe. The relative expression of the KM-HN-1 mRNA was calculated with the following formula (19):

\[
\text{Ratio} = \frac{(E_{KM-HN-1})_{\text{testis-sample}}}{(E_{\text{β-actin}})_{\text{testis-sample}}} \times 100
\]

Northern blot analysis was done as described previously (20). Integrity of RNA was checked by electrophoresis in formalin-MOPS (4-morpholinepropanesulfonic acid) gels. Gels with 20 μg of total RNA per lane were blotted onto nylon membranes. KM-HN-1–specific cDNA probe (bp 231–789) was used.

To prepare KM-HN-1–glutathione-S-transferase (KM-HN-1GST) fusion protein, a 1466-bp DNA fragment that was digested from a Homo sapiens cDNA clone IMAGE 4825416 (GenBank accession no. BG724227) and that corresponded to nucleotide position 149–1614 of KM-HN-1c DNA, was inserted into a prokaryotic expression vector pGEX-4T-3 (Amersham Pharmacia Biotech, Piscataway, NJ). This KM-HN-1 fragment covers NH2-terminal 488 amino acids (58.6%) of the whole KM-HN-1 consisting of 833 amino acids (Fig.1). Fusion protein synthesis was done as described previously (21) and was used for ELISA and for preparation of an anti-KM-HN-1 antibody by immunizing rabbits with KM-HN-1 GST fusion protein. The antiserum was affinity purified, with KM-HN-1 GST fusion protein and GST protein chromatography columns.

Immunocytochemical and Immunohistochemical Analyses. In immunocytochemical analysis, we used COS-7 and TE13 cell lines. To construct a mammalian expression vector, TACCATGCTG-3'. Quantification was achieved by comparison with an internal standard curve containing 10-fold dilutions of testis cDNA probe. The relative expression of the KM-HN-1 mRNA was calculated with the following formula (19):

\[
\text{Ratio} = \frac{(E_{KM-HN-1})_{\text{testis-sample}}}{(E_{\text{β-actin}})_{\text{testis-sample}}} \times 100
\]

Northern blot analysis was done as described previously (20). Integrity of RNA was checked by electrophoresis in formalin-MOPS (4-morpholinepropanesulfonic acid) gels. Gels with 20 μg of total RNA per lane were blotted onto nylon membranes. KM-HN-1–specific cDNA probe (bp 231–789) was used.

To prepare KM-HN-1–glutathione-S-transferase (KM-HN-1GST) fusion protein, a 1466-bp DNA fragment that was digested from a Homo sapiens cDNA clone IMAGE 4825416 (GenBank accession no. BG724227) and that corresponded to nucleotide position 149–1614 of KM-HN-1c DNA, was inserted into a prokaryotic expression vector pGEX-4T-3 (Amersham Pharmacia Biotech, Piscataway, NJ). This KM-HN-1 fragment covers NH2-terminal 488 amino acids (58.6%) of the whole KM-HN-1 consisting of 833 amino acids (Fig.1). Fusion protein synthesis was done as described previously (21) and was used for ELISA and for preparation of an anti-KM-HN-1 antibody by immunizing rabbits with KM-HN-1 GST fusion protein. The antiserum was affinity purified, with KM-HN-1 GST fusion protein and GST protein chromatography columns.

Immunocytochemical and Immunohistochemical Analyses. In immunocytochemical analysis, we used COS-7 and TE13 cell lines. To construct a mammalian expression vector,
we inserted full-length KM-HN-1 cDNA into pCAGGS-IRE-Neo-R, downstream of the CAG promoter (22, 23). COS-7 cells were transfected with the construct by lipofection with LipofectAMINE 2000 Reagent (Invitrogen Corp., Carlsbad, CA). Transfection and staining were done as described previously (24). We used FITC-labeled goat antirabbit IgG as a second antibody and propidium iodide for nuclear DNA staining. A confocal microscope (Fluoview FV300, Olympus) was used for observation. Immunohistochemical examinations were done as described previously (25). We stained 4-μm-thick sections of formalin-fixed and paraffin-embedded tissue samples with anti-KM-HN-1 antibody at a dilution of 1:20.

Detection by ELISA of a KM-HN-1-specific Antibody in Serum Samples. Detection and titration of an antibody specific to a NH2-terminal half fragment of KM-HN-1 was done, with indirect ELISA as described previously (21). Briefly, microtiter plates (96-well; NUNC, Roskilde, Denmark) were coated with GST-KM-HN-1 fusion protein in PBS (pH 7.4) for 16 hours at 4°C. The plates were then washed with PBS containing 0.05% Tween 20 (PBS-T) and blocked with 5% skim milk/PBS for 1 hour at room temperature. The plates were then washed and incubated for 2 hours at room temperature with serum samples diluted at 1:100 with 1% skim milk/PBS. The plates were washed, and 100 μL of horseradish peroxidase-conjugated mouse antihamster IgG diluted at 1:2000 was added to each well, followed by incubation at room temperature for 1 hour. The plates were washed, and then 100 μL of solution of o-phenylenediamine (Sigma Fast, Sigma Chemical Co., St. Louis, MO) were added to each well. After 30 minutes, the reaction was stopped by adding 100 μL of 3 mol/L H2SO4, and absorbance (A) at 490 nm was determined, with a Model 550 spectrophotometer (Bio-Rad, Hercules, CA). In addition to GST-KM-HN-1 fusion proteins as coating antigens, each serum sample was tested for reactivity against GST alone, as a control for nonspecific binding. The ratio of ΔGST-KM-HN-1 to ΔGST was calculated to express the degree of KM-HN-1-specific reactivity of antibodies above background. An absorbance ratio exceeding two SDs above the mean ratio of ΔGST-KM-HN-1 to ΔGST in 16 normal donors sera (2.15) was interpreted to be positive. Specificity of each positive sample was examined by testing reactivity after preincubation with GST-KM-HN-1. Confirmed positive samples had decreased GST-KM-HN-1 reactivity on ELISA compared with nonpreincubated sera. Distributions of absorbance values between healthy donors and various types of cancer patients were compared with two-tailed Student’s t test. The statistical significance of the difference in ratio of seropositive donors between cancer patients and healthy donors was assessed with a χ2 test.

Generation of KM-HN-1 Peptide-Specific CTL Lines. We searched for synthetic peptides (purity, >90%), derived from the sequence of KM-HN-1 with binding motifs for HLA-A*2402–encoded molecules (including tyrosine or phenylalanine at position 2 and isoleucine, leucine, or phenylalanine at position 9 or 10), with BIMAS software (BioInformatics and Molecular Analysis Section, Center for Information Technology, NIH, Bethesda, MD) and obtained from Bio-Synthesis, Inc. (Lewisville, TX; Fig. 1). An HIV nef-derived peptide (RYPLT-FGWCF) that can bind to HLA-A*2402–encoded molecules was used as a negative control (26). Dendritic cells were generated as described previously (27). The generated cells expressed dendritic cell-associated molecules, such as CD1a, CD83, CD86, and HLA-DR, on their cell surfaces (data not shown). CD8+ T cells were isolated, with CD8 microbeads (Miltenyi Biotec, Bergisch Gladbach, Germany), from peripheral blood mononuclear cells (PBMCs) of the same donors. A total of 2 × 106 CD8+ T cells were cultured with 2 × 105 irradiated (3500 cGy) autologous dendritic cells in RPMI 1640, supplemented with 10% heat-inactivated autologous serum, 5 ng/mL recombinant human interleukin (IL)-7 (PeproTech EC Ltd, London, United Kingdom), 100 units/mL penicillin, 100 μg/mL streptomycin, and 2 mmol/L l-glutamine, together with a KM-HN-1 synthetic peptide at a concentration of 1 μg/mL in a 16-mm-well plate. After culturing for 7 days, one half of the medium was exchanged for fresh culture medium supplemented with IL-7 and 10 units/mL recombinant human IL-2, and the cells were stimulated again by adding 2 × 105 irradiated (3500 cGy) autologous dendritic cells and KM-HN-1 peptide at a concentration of 1 μg/mL.

After a culture for an additional 7 days, the cells were stimulated a third time. The cells on day 20 of culture were tested for their peptide specificity by quantitating IFN-γ produced by CTLs, as described previously (28). Briefly, C1R-A*2402 cells (1 × 104), suspended in 100 μL RPMI 1640 supplemented with 10% fetal calf serum (assay medium), were seeded into round-bottomed microtiter wells and were incubated with or without synthetic peptide for 2 hours. Effector cells (1 × 105) suspended in 100 μL of assay medium were added to the well and were incubated for 16 hours; and the concentration of IFN-γ in the culture supernatants was measured with ELISA in duplicate assays. The KM-HN-1–specific CTL lines were cultured continuously in IL-2–containing culture medium, and irradiated autologous PBMCs and the KM-HN-1 peptide were added to the wells every week.

CTL Responses against Cancer Cell Lines. CTL response against cancer cell lines was measured by ELISA quantification of IFN-γ production as described above and by chromium release assay. Chromium release assay and cold target inhibition assay were done as described previously (29). Briefly, 51Cr (Na2CrO4) labeled target cells (1 × 104) suspended in 100 μL of assay medium were seeded into round-bottomed 96-well plates. Various numbers of effector cells suspended in 100 μL of assay medium were added to the well and were incubated for 4 hours, and 100 μL of supernatant were collected from each well. In the cold target inhibition assay, various numbers of unlabeled- and peptide pulsed-C1R-A*2402 cells were added to the well. The percentage specific lysis was calculated as follows:

\[
\text{cpm experimental release} - \text{cpm spontaneous release} \times 100
\]
\[
\text{cpm maximal release} - \text{cpm spontaneous release}
\]
RESULTS

Cloning of KM-HN-1 cDNA. We identified a 2.9-kb cDNA clone designated as KM-HN-1 (DNA Data Bank of Japan accession no. AB080722) after antibody-based screening of a cDNA expression library derived from normal testis with the use of serum from a patient with squamous cell carcinoma of the head and neck (SCCHN). This clone contained a 2499-bp complete open reading frame. The DNA sequence at the start codon in the open reading frame contained a Kozak consensus sequence (A/GNNATG) for high efficiency protein translation (30). A polyadenylation signal (AATAAA) was found in the 3' untranslated region, which suggested that this transcript had a complete 3' untranslated region sequence upstream of the polyadenylate tail. Comparisons with the nucleotide sequence of a gene encoding for hypothetical protein MGC33607 revealed the KM-HN-1 clone to be identical to MGC33607. This gene maps on chromosome 4, at 4q35.1 according to RefSeq. 5 KM-HN-1 contains a leucine zipper pattern, 3 coiled coil domains, and an endoplasmic reticulum membrane domain as judged by Psort 2 (http://psort.ims.u-tokyo.ac.jp/; Fig. 1).

KM-HN-1 Is Broadly Expressed in Cancer Tissues and Cancer Cell Lines but Expression in Normal Tissues Is Limited in Testis. As shown in Fig. 2A, a 2.9-kb transcript consistent with KM-HN-1 was expressed only in testis among normal tissues and was expressed in four of six SCCHN tissues and in several cancer cell lines, in Northern blot analysis. In tumor tissues, KM-HN-1 was expressed in a subset of a broad spectrum of tumors of different origins. As shown in Fig. 2B, some cancer tissues expressed a detectable amount of KM-HN-1 mRNA. Analysis of expression levels of mRNA in 17 normal tissues by RT-PCR detected specific mRNA only in testis (Fig. 2C). KM-HN-1 expression levels in various normal and cancer tissues were determined by quantitative RT-PCR, and these data were evaluated by calculating relative ratio to the KM-HN-1 expression level in the human testis. Although relative KM-HN-1 expression levels in all normal tissues except testis are under 0.02, those in five of six tongue cancers, three of five melanomas, one of four hepatocellular carcinomas (HCCs), one gastric cancer, and one pancreatic cancer tissues are above 0.1 (Table 1). Furthermore, expression of KM-HN-1 mRNA was detected in various types of cancer cell lines established from SCCHN, esophageal cancer, lung cancer, gastric cancer, HCC, melanoma, pancreatic cancer, and colon cancer by RT-PCR analysis (Table 2).

Nuclear Localization of KM-HN-1 Protein. To determine the specificity of the anti-KM-HN-1 antibody, we carried out indirect immunofluorescence staining analysis with KM-HN-1–transfected COS-7 cells. COS-7 cells were transiently transfected with a KM-HN-1 expression vector and were grown on fibronectin-coated coverslips. The cells were doubly stained with propidium iodide and anti-KM-HN-1 polyclonal antibody, and signals were detected with a FITC-labeled goat antirabbit IgG antibody. No KM-HN-1 staining signal was observed when COS-7 cells were transfected with a vector only. On the other hand, when KM-HN-1 expression vector was used for transfection, about 20% of the COS-7 cells were stained (data not shown). Forced expression of KM-HN-1 did not induce morphologic changes in COS-7 cells. To determine the subcellular

compared by two-tailed Student t test. The cutoff value (2.15) is the mean plus two SD for healthy donors.

* The relative expression of the KM-HN-1 mRNA was calculated using the following formula: ratio = (EKM-HN-1/CP)/(Eβ-actin/CP) × 100.

localization of KM-HN-1 protein, we also stained TE13 cells (esophageal cancer cell lines expressing abundant intrinsic KM-HN-1 protein) with anti-KM-HN-1 antibody. In interphase, KM-HN-1 staining was detected throughout the nucleus, especially bright at the nuclear boundary with weak staining in the cytoplasm (Fig. 3A–C). During mitosis, KM-HN-1 colocalized with chromosomes (Fig. 3D–O).

Expression of KM-HN-1 Protein in Testis and Several Cancer Tissues. To determine whether the anti-KM-HN-1 antibody could also recognize KM-HN-1 expressed in paraffin-embedded tissues, we analyzed testicular tissue immunohistochemically. KM-HN-1 expression in mature testis was found to occur only in spermatogenic cells, mainly in the cytoplasm of spermatocytes and occasionally in that of spermatogonia (Fig. 4A). The expression was heterogeneous, and only a fraction of spermatocytes was stained at the nucleus. Neither interstitial cells nor Sertoli cells were stained with the anti-KM-HN-1 antibody. Using this antibody, we next examined expression of KM-HN-1 in several tumor tissues. KM-HN-1 was stained in 4 of 10 esophagus, 1 of 2 breast, and 1 of 3 colon cancer tissues (Fig. 4E, F, and G). In these cells, staining was observed mostly in the cytoplasm with nuclear staining being less prominent. In contrast, KM-HN-1 was not stained in the normal esophagus, breast, or colon tissues (Fig. 4B, C, and D).

§ The statistical significance of difference in distributions of Absorbance values between healthy donors and various types of cancer patients was compared by two-tailed Student’s t test.
Identification of a Novel CT Antigen, KM-HN-1

against GST, ELISA reactivity was blocked by prior incubation of sera with an excess amount of purified GST-KM-HN-1 (data not shown). These results confirmed the specificity of IgG to KM-HN-1 in these patients and suggest that KM-HN-1 could elicit humoral immune responses in patients with a variety of tumors.

Association between KM-HN-1 Expression in Cancer and Presence of KM-HN-1 Antibody in Patients’ Sera. Both fresh-frozen tumor specimens and serum samples were available from 13 cancer patients (5 melanomas, 4 HCC, and 4 tongue cancer). Tumors were tested for KM-HN-1 expression by quantitative RT-PCR, and sera were assayed for KM-HN-1 antibody by ELISA (Table 3). In this series of 13 patients, 5 had both KM-HN-1-positive tumors and KM-HN-1 antibodies. No KM-HN-1 antibody was detected in five patients with KM-HN-1 negative tumors. Three patients had KM-HN-1-positive tumors and no detectable KM-HN-1 antibody. Although the total numbers of samples were small, the association between KM-HN-1 expression in cancer and presence of KM-HN-1 antibody in patients’ sera was statistically significant (P < 0.05).

Establishment of CTL Lines Specific to KM-HN-1 Peptide. We attempted to generate KM-HN-1-specific CTLs from four HLA-A*2402-positive healthy individuals and four HLA-A*2402-positive SCCHN patients, by using KM-HN-1 peptide-pulsed dendritic cell. After three stimulations, CTL activity against peptide-pulsed C1R-A*2402 cells was examined by measuring IFN-γ production to assess peptide specificity. As shown in Fig. 6A, CTLs recognizing KM-HN-1 derived peptide were generated from all SCCHN patients and two of four healthy donors. The peptide-reactive CTL lines specific to HN-196–204, HN-1499–508, and HN-1770–778 were induced from two (SCCHN3 and HD1), three (SCCHN1, SCCHN3, and HD1), and four (SCCHN2, SCCHN4, HD1, and HD2) donors, respectively. The background levels of IFN-γ production in response to peptide unpulsed C1R-A*2402 cells were less than 20 pg/mL. These CTL lines did not produce IFN-γ when exposed to C1R-A*2402 cells pulsed with an HIV-1 nef-derived peptide that had a high binding affinity to HLA-A24, or when exposed to KM-HN-1 peptide-loaded parent cell line, C1R cells, negative for HLA-A*2402 (data not shown). These data indicate that these CTL activities were KM-HN-1–derived peptide-specific and restricted by HLA-A*2402 gene product.

To investigate whether 3 KM-HN-1–derived peptides, recognized by CTL lines, are naturally processed and presented by HLA-A*2402-encoded molecules, SCCHN cell line HSC-4 (HLA-A*2402 positive, KM-HN-1 negative) and HSC-4-HN-1, the HSC-4 cells transfected with full-length KM-HN-1 cDNA, were used as target cells. As shown in Fig. 6B, CTL lines induced by HN-196–204, HN-1499–508 produced substantial amounts of IFN-γ when exposed to HSC-4–HN-1, but CTL lines induced by HN-1770–778 did not do so. The background levels of IFN-γ production by the cells in response to HSC-4 were less than 30 pg/mL in Fig. 6B.

Reactivity and Cytotoxicity of CTL Lines against Cancer Cell Lines. HLA-A24 expression in the cancer cell lines was examined by staining with anti-HLA-A24 monoclonal antibody (One Lambda, Inc., Canoga Park, CA) followed by flow cytometry and genotyping, and KM-HN-1 expression was examined by Northern blot analyses. Among the seven cell lines examined, TE9 were negative for HLA-A24, and HSC-4 were negative for KM-HN-1. Because the total amount of blood obtained from cancer patients was limited, we could use CTL lines from cancer patients only for limited experiments. The CTL reactivity was detected when CTLs were exposed to cancer cell lines positive for both HLA-A24 and KM-HN-1. Representative data are shown in Fig. 7A, B, and C. CTL lines induced by HN-196–204, HN-1499–508, and HN-1770–778 peptide-pulsed dendritic cell. After three stimulations, CTL activity against peptide-pulsed C1R-A*2402 cells was examined by measuring IFN-γ production to assess peptide specificity. As shown in Fig. 6A, CTLs recognizing KM-HN-1 derived peptide were generated from all SCCHN patients and two of four healthy donors. The peptide-reactive CTL lines specific to HN-196–204, HN-1499–508, and HN-1770–778 were induced from two (SCCHN3 and HD1), three (SCCHN1, SCCHN3, and HD1), and four (SCCHN2, SCCHN4, HD1, and HD2) donors, respectively. The background levels of IFN-γ production in response to peptide unpulsed C1R-A*2402 cells were less than 20 pg/mL. These CTL lines did not produce IFN-γ when exposed to C1R-A*2402 cells pulsed with an HIV-1 nef-derived peptide that had a high binding affinity to HLA-A24, or when exposed to KM-HN-1 peptide-loaded parent cell line, C1R cells, negative for HLA-A*2402 (data not shown). These data indicate that these CTL activities were KM-HN-1–derived peptide-specific and restricted by HLA-A*2402 gene product.

To investigate whether 3 KM-HN-1–derived peptides, recognized by CTL lines, are naturally processed and presented by HLA-A*2402-encoded molecules, SCCHN cell line HSC-4 (HLA-A*2402 positive, KM-HN-1 negative) and HSC-4-HN-1, the HSC-4 cells transfected with full-length KM-HN-1 cDNA, were used as target cells. As shown in Fig. 6B, CTL lines induced by HN-196–204, HN-1499–508 produced substantial amounts of IFN-γ when exposed to HSC-4–HN-1, but CTL lines induced by HN-1770–778 did not do so. The background levels of IFN-γ production by the cells in response to HSC-4 were less than 30 pg/mL in Fig. 6B.

Reactivity and Cytotoxicity of CTL Lines against Cancer Cell Lines. HLA-A24 expression in the cancer cell lines was examined by staining with anti-HLA-A24 monoclonal antibody (One Lambda, Inc., Canoga Park, CA) followed by flow cytometry and genotyping, and KM-HN-1 expression was examined by Northern blot analyses. Among the seven cell lines examined, TE9 were negative for HLA-A24, and HSC-4 were negative for KM-HN-1. Because the total amount of blood obtained from cancer patients was limited, we could use CTL lines from cancer patients only for limited experiments. The CTL reactivity was detected when CTLs were exposed to cancer cell lines positive for both HLA-A24 and KM-HN-1. Representative data are shown in Fig. 7A, B, and C. CTL lines induced by HN-196–204, HN-1499–508, and HN-1770–778 produced substantial amounts of IFN-γ in response to all cancer cell lines positive for both HLA-A24 and KM-HN-1. Cytotoxic activity of these CTL lines was also examined. These CTL lines exhibited cytotoxicity only against TE3 and TE11, which were positive for both HLA-A24 and KM-HN-1, but not against TE9 and HSC-4 (Fig. 8A–G).

To further confirm that the cytotoxicity of these CTL lines against cancer cells was mediated by specific recognition of endogenously processed KM-HN-1, we did a cold target inhibition assay as shown in Fig. 8J, K, and L. In the presence of cold target C1R-A*2402 loaded with HN-196–204, HN-1499–508, or HN-1770–778 peptides, cytotoxic activity of these CTL lines against PC-9 (Fig. 8J and K) or IFN-γ treated TE13 (Fig. 8L) was markedly inhibited, whereas the addition of HIV-1 nef-derived peptide-loaded or -unloaded C1R-A*2402 had no effect on cytotoxicity. These findings clearly indicate
that HN-1\textsubscript{196–204}, HN-1\textsubscript{499–508}, and HN-1\textsubscript{770–778} peptides are naturally processed from KM-HN-1 protein in cancer cells, expressed in the context of HLA-A24, and recognized by KM-HN-1–specific CTL lines to induce cytotoxicity against cancer cells.

Effects of IFN-\gamma on Susceptibility of Cancer Cells to CTL-Mediated Cytotoxicity. Until now, several antigenic peptides that were processed exclusively by immunoproteasome but not standard proteasome, were reported (31, 32). CTL lines specific to HN-1\textsubscript{770–778} peptide derived from four different donors were reactive against HN-1\textsubscript{770–778} peptide-pulsed C1R-A*2402 cells but not against HSC-4-HN-1 (Fig. 6A and B). We thought that this peptide might be processed by immunoproteasome. Most nonlymphoid cells, be they normal or tumoral, constitutively express standard proteasomes and switch to immunoproteasomes when exposed to

Fig. 4 Immunohistochemical staining of KM-HN-1 antigen in normal and cancer tissues by using avidin-biotin complex method and 3,3′-diaminobenzidine chromogen. A, in testis, seminiferous tubules were positively stained with strong intratubular staining of mostly spermatogenic cells, whereas no reactivity with spermatids or with Sertoli cell or interstitial tissue was observed. B, C, and D, KM-HN-1 staining was not detected in the normal esophagus, breast, or colon. E, Heterogeneous KM-HN-1 staining was observed in esophageal cancer. Homogeneous KM-HN-1 staining was observed in both breast cancer (F) and colon cancer (G). $\times$200. Scale bar, 100 \textmu m.

Fig. 5 Quantitation of KM-HN-1–specific IgG measured by ELISA in sera from age-matched healthy donors and patients with various types of cancer. Serum samples were diluted at 1:100 and were analyzed by ELISA to detect antibodies reactive to GST-KM-HN-1 fusion protein and GST alone. The ratio of the absorbance (A) for GST-KM-HN-1 to the absorbance for GST was calculated to express the degree of specific reactivity above background. Dashed line, the upper normal value (two SDs above the mean value in healthy donors).
Identification of a Novel CT Antigen, KM-HN-1

* The relative expression ratio of the KM-HN-1 mRNA was calculated using the following formula: ratio = (E<sub>KM-HN-1</sub>)<sup>ΔΔCT</sup> / (E<sub>β-actin</sub>)<sup>ΔΔCT</sup> × 100.

† Antibody titer was determined using indirect ELISA with KM-HN-1-GST fusion protein. The cutoff value (2.15) is the mean plus two SD for healthy donors’ sera; positive values are underlined.

IFN-γ (33). Therefore, we investigated effects of IFN-γ on the susceptibility of cancer cells to CTL-mediated cytotoxicity. Target cell lines (HSC-4 and HSC-4-HN-1) were pretreated with IFN-γ according to the protocol described in Materials and Methods. CTL lines specific to HN-1<sub>770–778</sub> peptide produced IFN-γ in response to IFN-γ-treated target cells (Fig. 6C). Furthermore, HN-1<sub>196–204</sub> and HN-1<sub>199–208</sub> peptide-specific CTL lines also showed increased IFN-γ production in response to IFN-γ-treated target cells. All of CTL lines that were reactive to peptide-pulsed C1R-A2402 cells produced substantial amounts of IFN-γ in response to HSC-4-HN-1 treated with IFN-γ, but not in response to HSC-4 treated with IFN-γ (data not shown). The background levels of IFN-γ production by the cells in response to HSC-4 were under 50 pg/mL in Fig. 6C. Next, we investigated effects of IFN-γ on the presentation of naturally processed KM-HN-1 peptide in cancer cell lines. Cytotoxic activities of all of these CTL lines tested were also increased when TE13 was pretreated with IFN-γ (Fig. 6H and I), but not when TE9 and HSC-4 were pretreated with IFN-γ (data not shown).

**DISCUSSION**

A prerequisite for a broader application of antigen-specific immunotherapy for cancer is the molecular definition of antigens that are specifically expressed in commonly occurring neoplasms, e.g., breast, lung, prostate, or colorectal carcinoma. The recognition that members of the MAGE, BAGE, GAGE, HOM-MEL-40, and NY-ESO-1 gene families form a class of tumor antigens with restricted expression confined to cancer and testis has led to the designation of CT antigens. This characteristic expression profile suggested that testicular tissue is a prime candidate source for the identification of additional CT antigens by SEREX. To further increase the yield of unidentified CT antigens, we applied SEREX with serum from a SCCHN patient and a testis cDNA expression library to identify KM-HN-1.

Although KM-HN-1 contains no Pfam motif (http://pfam.wustl.edu/), it does consistently exhibit a low level (<20%) of substantial homology with CENP-F (centromere protein F) and...
stimulated CTLs. * Furthermore, some CT antigens, e.g., human spermatogonia (40). As shown in Fig. 4, our data were similar to the observations in previous studies. Third, KM-HN-1 is immunogenic in cancer patients: KM-HN-1 elicited humoral immune responses in many types of cancer patients (44, 45), we looked for the KM-HN-1–specific antibody in the sera of cancer patients with ELISA methods. Surprisingly an anti-KM-HN-1 IgG was observed in 14 to 100% of all types of cancer patients tested, on the other hand this was not observed in healthy donors (Fig. 5; Table 2). Thereby quantification of anti-KM-HN-1 IgG in sera may provide us a new diagnostic method for various types of cancer. However, a statistically significant association between KM-HN-1 antibody status and clinical characteristics of patients (age, sex, stage) was not evidenced (data not shown).

In this study, we used synthetic KM-HN-1 peptides consisting of HLA-A24 binding motifs for the generation of CTLs from PBMCs, because the HLA-A24 allele is the most frequent HLA class I allele in the Japanese population and is found in 60% of the Japanese (95% of these cases are genotypically A*2402), in 30% of Chinese, and in 20% of Caucasians (46). Of the 13 synthetic peptides used, three peptides (HN-1196–204, HN-1499–508, and HN-1770–778) induced peptide-specific CTL lines. CTLs recognizing KM-HN-derived peptide were generated from all four SCCHN patients and two of four healthy donors. Although the KM-HN-1–specific CTL-precursor frequency of SCCHN patients seemed to be higher than that of healthy donors, peptide-specific CTLs were not detected by intracellular staining of IFN-γ with PBMCs that were stimulated with KM-HN-1 peptides ex vivo, in either cancer patients or healthy donors. Peptide-specific CTLs could be detected after two stimulations with antigenic peptide, but a statistically significant difference in frequency of IFN-γ producing CTLs (1–4% of CD8+ T cell) between cancer patients and healthy donors was not observed (data not shown).

Further examination showed that CTL lines specific to only two (HN-1196–204 and HN-1499–508) of these peptides lysed KM-HN-1 transfectant (HSC-4-HN-1), but all CTL lines reactive to peptide-pulsed C1R-A*2402 lysed HSC-4-HN-1 pretreated with IFN-γ (Fig. 6). Similar results are shown for CTL activities against cancer cell lines (Fig. 8). When cancer cell lines were treated with IFN-γ, the KM-HN-1 mRNA level did not change (data not shown). In general, IFN-γ induces several changes in cancer cells, e.g., up-regulation of MHC class I
Identification of new CTL epitopes in different tumor antigens will allow for development of multiantigenic (epitope-based) tumor vaccines, which will probably be useful to circumvent tumor escape from immune systems by losing expression of antigen. In this study, we found a novel human cancer/testis antigen, KM-HN-1. KM-HN-1 gene is expressed in many types of cancer, and a humoral immune response to KM-HN-1 protein is detected in many cancer patients. Furthermore, three peptides derived from KM-HN-1 could induce HLA-A24-restricted and tumor-reactive CTL lines. These results suggest that KM-HN-1 might be a good candidate for the development of a cancer vaccine applicable to various types of cancer patients.

ACKNOWLEDGMENTS

We thank Drs. M. Takiguchi (Kumamoto University, Kumamoto, Japan) and K. Itoh (Kurume University, Kurume, Japan), and the Cell Resource Center for Biomedical Research, Institute of Development, Aging and Cancer, Tohoku University (Sendai, Japan) for providing tumor samples, cell lines and helpful suggestions. We also thank Dr. T. Yamamoto and T. Kubo (Department of Molecular Pathology, Kumamoto University) for technical assistance with the immunohistochemical analyses, and M. Ohara (Fukuoka) for helpful comments.
