Abstract

Purpose: The CD38 cell surface antigen is expressed in diverse hematologic malignancies including multiple myeloma, B-cell non-Hodgkin lymphoma (NHL), B-cell chronic lymphocytic leukemia, B-cell acute lymphoblastic leukemia (ALL), and T-cell ALL. Here, we assessed the antitumor activity of the anti-CD38 antibody SAR650984.

Experimental Design: Activity of SAR650984 was examined on lymphoma, leukemia and multiple myeloma cell lines, primary multiple myeloma samples, and multiple myeloma xenograft models in immunodeficient mice.

Results: We identified a humanized anti-CD38 antibody with strong proapoptotic activity independent of cross-linking agents, and potent effector functions including complement-dependent cytotoxicity, antibody-dependent cell-mediated cytotoxicity, and antibody-dependent cellular phagocytosis (ADCP), equivalent in vitro to rituximab in CD20⁺ and CD38⁺ models. This unique antibody, termed SAR650984, inhibited the ADP-ribosyl cyclase activity of CD38, likely through an allosteric antagonism as suggested by 3D structure analysis of the complex. In vivo, SAR650984 was active in diverse NHL, ALL, and multiple myeloma CD38⁺ tumor xenograft models. SAR650984 demonstrated single-agent activity comparable with rituximab or cyclophosphamide in Daudi or SU-DHL-8 lymphoma xenograft models with induction of the proapoptotic marker cleaved capase-7. In addition, SAR650984 had more potent antitumor activity than bortezomib in NCI-H929 and Molp-8 multiple myeloma xenograft studies. Consistent with its mode of action, SAR650984 demonstrated potent proapoptotic activity against CD38⁺ human primary multiple myeloma cells.

Conclusion: These results validate CD38 as a therapeutic target and support the current evaluation of this unique CD38-targeting functional antibody in phase I clinical trials in patients with CD38⁺ B-cell malignancies. Clin Cancer Res; 20(17); 4574–83. ©2014 AACR.

Introduction

Rituximab, a chimeric anti-CD20 antibody, dramatically improved the treatment outcome of both indolent and aggressive non-Hodgkin lymphoma (NHL) through its use as a single agent or in combination with chemotherapy (1, 2). Although rituximab ultimately depletes B cells through binding to CD20, its mechanism of action is attributed to a combination of direct apoptosis induction and activation of immune effector mechanisms, including antibody-dependent cell-mediated cytotoxicity (ADCC) and phagocytosis (ADCP) and complement-dependent cytotoxicity (CDC; ref. 3). Despite the success of rituximab, incomplete treatment responses and emergence of resistance represent important limitations (1). In an attempt to overcome these limitations, a plethora of second-generation anti-CD20 antibodies has been introduced into clinical development, most notably ofatumumab and obinutuzumab which have gained regulatory approval in B-cell chronic lymphocytic leukemia (CLL; ref. 4). CD20 expression is confined to a B-cell subset, restricting the utility of these agents to patients with CLL and B-cell NHL. Therefore, identification of new targets with a broader expression spectrum and potential for

Translational Relevance

The CD38 antigen is a promising target for an antibody-based therapeutic as it is expressed in a number of hematologic malignancies including multiple myeloma, B-cell non-Hodgkin lymphoma, B-cell chronic lymphocytic leukemia, B-cell acute lymphoblastic leukemia (ALL), and T-cell ALL. On the basis of the success of rituximab in treating CD20⁺ lymphoma, targeting CD38 with a functional antibody is a promising therapeutic approach for these diverse indications. SAR650984, a novel anti-CD38 antibody described here, induces a unique combination of effects on cancer cells including complement-dependent cytotoxicity, antibody-dependent cell-mediated cytotoxicity, antibody-dependent cellular phagocytosis, and apoptosis, and demonstrates potent in vitro and in vivo activity against cells derived from these malignancies. Consequently, clinical trials with this antibody in patients with CD38⁺ hematologic malignancies are on-going (NCI:10184252, NCT01749969), with initial signs of promising efficacy.

Antibody mechanisms similar to rituximab could yield novel antibody therapeutics for a wider range of hematologic malignancies.

The cell surface molecule CD38 represents such an opportunity because it is expressed in multiple hematologic malignancies derived from both lymphoid and myeloid lineages, including multiple myeloma, a CD20 negative B-cell malignancy (5). CD38 is a 45 kDa type II transmembrane glycoprotein that has been described as both a receptor and a multifunctional enzyme involved in the production of nucleotide-metabolites (6–8). It has been proposed to associate with cell surface proteins in lipid rafts, regulate cytoplasmic Ca²⁺ flux, and mediate signal transduction in lymphoid and myeloid cells (9–12). During hematopoiesis, CD38 is expressed on CD34⁺ stem cells and lineage-committed progenitors of lymphoid, erythroid, and myeloid cells, while pluriptotent early stem cells are defined as CD34⁺CD38⁻. CD38 expression is absent during the intermediate stages of lymphocyte maturation, then reappears during the final stages of maturation, and continues through the plasma cell stage (13–16).

CD38 expression is an important prognostic factor in B-CLL that identifies patients with aggressive disease and poor survival (17–19). It has been proposed that CD38 plays a role in the proliferation and survival of CLL cells (20). High CD38 expression has been reported on plasma cells as well as their malignant counterparts, multiple myeloma cells, leading to its widespread use as a surface marker, combined with CD138, to enumerate malignant myeloma cells in patient bone marrow (5, 21). Overall, CD38 expression in hematologic malignancies and its correlation with disease progression make CD38 an attractive target for antibody-based therapeutics. Several anti-human CD38 antibodies differing in their functional properties against various malignant cells and cell lines have been described in the literature (10, 22–27). A recently developed antibody, daratumumab, is currently undergoing clinical trials in patients with multiple myeloma and reported to have a manageable safety profile and early signs of efficacy (28–30). Another anti-CD38 antibody, MOR202, is being evaluated in a phase I/IIa trial in patients with relapsed/refractory multiple myeloma (31, 32).

Here, we describe the generation of a new humanized anti-CD38 antibody, SAR650984, selected for its multiple mechanisms of action. SAR650984 demonstrated potent proapoptotic activity in the absence of cross-linking agents, elicited immune effector mechanisms such as CDC, ADCC, and ADCP against CD38⁺ malignant cells, and in addition strongly inhibited CD38 enzymatic activity. This unique combination of activities translated into strong in vivo efficacy of SAR650984 against diverse CD38⁺ tumor xenograft models.

Materials and Methods

Cell culture

Ramos, Raji, Daudi, and Namalwa lymphoma cells were obtained from the American Type Culture Collection (ATCC). All other cell lines were obtained from Deutsche Sammlung von Mikroorganismen und Zellkulturen (DSMZ). Cells were cultured in RPMI-1640 medium supplemented with 10% FBS, 2 mmol/L glutamine, and 1% penicillin-streptomycin (Life Technologies) at 37°C in a humidified 5% CO₂ incubator.

Antibody generation

CD38-binding murine monoclonal antibodies were generated by standard hybridoma technology following immunizations with murine 300-19 cells transfected to express the full-length human CD38 antigen. Antibodies were chimerized (ch) as huGlG1-x and humanized (hu) by variable domain resurfacing (33). Chimeric antibodies, chHB7 and chOKT10, were produced on the basis of sequences derived from their respective murine hybridomas (ATCC HB-136, CRL-8022). Ab005 (a surrogate antibody for daratumumab) and huAT13/5 were produced on the basis of sequences corresponding to sequences 17 and 12 from US7829673 (34). CAA03366 and CAA03368 for huAT13/5). IB4 and SUN-4B7 were a gift from F. Malavasi, University of Turin, Italy. Rituximab, cyclophosphamide, and bortezomib were obtained from commercial sources.

Apoptosis induction

Cells were incubated at 2 × 10⁵ cells/ml in complete medium (RPMI-1640, 10% FBS, 2 mmol/L l-glutamine) with 1.5 µg/ml (10 nmol/L) of indicated antibodies for 20 hours at 37°C with 5% CO₂. Cells were stained with Annexin V-FITC in accordance with the manufacturer’s instructions (Life Technologies). Samples were analyzed by flow cytometry on a FACSCalibur flow cytometer with CellQuest Pro (v5.2) for acquisition control and data analysis (both BD Biosciences).
**Binding assay**

Antibodies were incubated with $5 \times 10^4$ cells per assay in RPMI-1640 with 2% normal goat serum and 0.1% sodium azide (both Sigma-Aldrich) for 3 hours on ice followed by incubation with FITC-conjugated goat-anti-mouse or anti-human IgG antibody (Jackson ImmunoResearch) for 1 hour on ice. Samples were analyzed on a FACSCalibur flow cytometer as above. Sigmoidal dose-response curves were generated and EC$_{50}$ values calculated using GraphPad Prism (GraphPad Software).

**Expression analysis**

Cells were incubated in PBS with 0.1% sodium azide and 0.5% BSA (Sigma-Aldrich) at $2 \times 10^6$ cells per assay with 5 µg/mL anti-CD38-PE or 16 µg/mL anti-CD20-PE (BD Biosciences) for 2 hours on ice. Samples were washed, fixed, and acquired in conjunction with QuantiBRITE beads (BD Biosciences) by flow cytometry according to the manufacturer’s instructions. Values for antibodies bound per cell (ABC) were extrapolated from the standard curve.

**ADCC, ADCP, and CDC assays**

ADCC activity with isolated natural killer (NK) cells and $5 \times 10^5$ target cells at an effector:target (E:T) ratio of 3:1 was measured by lactate dehydrogenase release (Cytotoxicity Detection Kit, Roche) after 4-hour incubation using standard protocols (34). The degree of specific lysis was calculated as follows: %lysis = (experimental release – spontaneous release)/(maximum release - spontaneous release) $\times$ 100.

Monocyte-derived macrophages were prepared by isolating monocytes from peripheral blood using CD14$^+$ beads and culturing them in the presence of 50 ng/mL hGM-CSF (both Miltenyi Biotec) for 7 days. ADCC was evaluated using $2 \times 10^5$ Ramos target cells labeled with PKH26 (Sigma-Aldrich), then incubated with antibodies and isolated human monocyte-derived macrophages in round-bottom 96-well plates at 37°C for 3 hours at an E:T ratio of 3:1. Subsequently, samples were stained with anti-CD11b-Alexa Fluor-488 (AF; Life Technologies) to identify macrophages, washed and fixed with 4% paraformaldehyde. Cell-associated fluorescence of PKH26 (FL2, Target cells) and AF (FL1, Macrophages) was measured by flow cytometry using a FC500 cytometer. Dual-labeled cells were considered as phagocytic events, and the degree of phagocytosis was determined as: %phagocytosis = 100 x [# of FL2+FL1+ events/ (# of FL2+FL1+ events + # of FL2+FL1- events)].

In CDC assays, antibodies were incubated with $5 \times 10^4$ target cells per well in the presence of 5% human complement (Sigma-Aldrich) for 2 hours as previously described (35). Viability of remaining cells was determined by AlamarBlue assays (Life Technologies).

**Primary multiple myeloma samples**

Bone marrow aspirates from patients with multiple myeloma were obtained from Hospital Edouard Herriot (Lyon, France) after written informed consent under protocols approved by an Institutional Review Board. Mononuclear cells were prepared by standard Ficoll-Paque centrifugation. Cells were incubated at $10^6$ cells per sample with 100 µg/mL SAR650984 for 18 hours at 37°C in culture media containing 50% autologous serum (all patient samples contained > 18 mg/mL of IgG; see Supplementary Table S1). Samples were stained with anti-CD38-APC (HB7, BD Biosciences) and anti-CD138-PC5 (BA38, Beckman Coulter) antibodies to identify multiple myeloma cells and the degree of apoptosis were measured by Annexin-V-FITC staining. Samples were analyzed by flow cytometry on a FACSCalibur or a FACS Canto II (both BD Biosciences).

**Enzymatic activity assay**

A recombinant soluble human CD38-Fc fusion protein was produced, and enzymatic activity assays carried out as described in the Supplementary Data section (36).

**3D structure analysis**

Crystals of the non-glycosylated soluble human CD38 antigen (extracellular domain R45-I300) and the SAR650984 Fab fragment were obtained and analyzed as described in the Supplementary Data section. High-resolution data for crystals up to 1.53 Å were collected at beamline ID-29 at the European Synchrotron Radiation Facility (ESRF).

**In vivo xenograft studies**

Female CB.17 SCID mice (Charles River Laboratories) were inoculated subcutaneously with $1 \times 10^6$ cells. Treatment was initiated as indicated and tumor volumes were measured twice weekly for the duration of the study. %T/C was calculated as the median tumor volume of each treated (T) group divided by the median tumor volume of the vehicle control (C) group. Activity was assessed according to National Cancer Institute (NCI, Bethesda, MD) standards (%T/C $\leq$ 42% = active, %T/C value $\leq$ 12% = highly active).

For survival studies, SCID mice were inoculated intravenously with $5 \times 10^6$ cells per mouse through lateral tail vein injection. Animals were sacrificed when hind leg paralysis was present or body weight decreased by >20% of pretreatment weight. Kaplan–Meier analysis was performed for survival studies and %increase of lifespan (%ILS) was calculated as %ILS = 100 x (median survival of treated group – median survival of control group)/median survival of control group. In accordance with NCI standards, %ILS > 25% was considered active. Induction of cleaved caspase-7 in tumors was evaluated by immunoblot analysis as described in the Supplementary Data section.

**Results**

**Antibody generation and selection**

We generated a large panel of murine monoclonal antibodies that specifically bound to human CD38 (HuCD38). To identify antibodies with intrinsic anticancer cell activity, antibodies were screened for their ability to induce apoptosis in lymphoma cells in the absence of any cross-linking agents. One of the antibodies identified had notably strong proapoptotic activity, inducing 35% Annexin V-positive...
Daudi cells compared with 6% Annexin V-positive cells in the absence of antibody (Fig. 1A). In contrast, other anti-CD38 antibodies generated in our screen, such as clones 7 and 23, did not induce a significant increase in Annexin V staining of cells. Previously generated anti-CD38 antibodies huAT13/5, chOKT10, IB4, and SUN-4B7 also resulted at best in a minor (14% or less) increase in the percentage of Annexin V-positive Daudi cells. This murine lead clone was therefore chosen for further analysis based on its unique proapoptotic activity and humanized by variable domain resurfacing. The chimeric and humanized versions of the lead clone retained specific, high-affinity binding to human CD38 with an apparent Kd of 0.2 nmol/L (Fig. 1B). Its humanized IgG1 version was designated as SAR650984.

**Functional activity of the humanized anti-CD38 antibody SAR650984**

Superior proapoptotic activity by SAR650984 over rituximab in the absence of cross-linking agents was seen in Raji, Daudi, and Ramos lymphoma cells, which express CD20 and CD38 at similar levels (Fig. 2A and B). In addition, SAR650984 induced apoptosis in CD38\(^+\)CD20\(^-\) SU-DHL-8 diffuse large B-cell lymphoma (DLBCL) cells, Molp-8 multiple myeloma cells, and DND-41 T-ALL cells (Fig. 2A).

Immune effector functions mediated by rituximab were reported to contribute to its clinical activity. We therefore compared immune effector activities of SAR650984 in CD38\(^+\)CD20\(^+\) cell lines with those of rituximab. SAR650984 induced strong CDC in the presence of human serum as well as strong ADCC via human NK cells in Raji and Daudi cells, with similar activity as rituximab (Fig. 2C and D). In addition, SAR650984 mediated ADCP with human macrophages against Ramos cells to a similar extent as rituximab at 10 μg/mL (Fig. 2E).

**SAR650984 activity against a panel of diverse cell lines**

CD38 is expressed on a wider range of malignant cell types than CD20, providing the potential for an expanded utility of a therapeutic anti-CD38 antibody (5). We therefore characterized a larger panel of cell lines for their CD38 expression level and SAR650984 in vitro activity.

CD38 levels were determined by quantitative flow cytometry and ranged from 790,000 to 59,000 ABC in the 15 cell lines tested representing B-cell NHL, multiple myeloma, B-CLL, T-cell acute lymphoblastic leukemia (ALL), and B-cell ALL (Fig. 3A). Most notably, the three multiple myeloma cell lines evaluated ranked among the six highest expressors with 790,000 to 233,000 ABC. SAR650984 induced apoptosis in eight of 15 evaluated cell lines with up to 90% Annexin V-positive cells and EC\(_{50}\) values from 2 to 16 ng/mL (Fig. 3B). Strong CDC activity was seen in seven of 15 cell lines evaluated with up to 90% maximum lysis and EC\(_{50}\) values varying widely from 8 to 230 ng/mL (Fig. 3C). SAR650984-mediated potent ADCC against all 15 cell lines evaluated with maximum lysis of 30% to 90% of target cells and EC\(_{50}\) values of the dose–response ranged from approximately 0.2 to 8 ng/mL (Fig. 3D). SAR650984 mediated ADCP with 60% phagocytosed Ramos cells, compared with 25% in untreated samples, with an EC\(_{50}\) value of 5 ng/mL (Fig. 3E). Although ADCC activity was seen against all CD38\(^+\) cell lines tested regardless of CD38 expression level, apoptosis induction and CDC activity were most often seen against cell lines with the highest CD38 levels (Fig. 3A).

Binding of SAR650984 to normal human peripheral blood cells was assessed by flow cytometry. SAR650984 specifically bound to monocytes and T cells (Supplementary Fig. S1A and S1B) with the same affinity seen on tumor cells. We observed low levels of CD38 expression in normal human blood cells with 3,000 to 14,000 ABC, much lower than levels of CD20 expression on B cells (Supplementary Fig. S1C). SAR650984 treatment did not deplete peripheral blood cells cultured in vitro (Supplementary Fig. S1D), whereas rituximab resulted in B-cell depletion and alemtuzumab in both B- and T-cell depletion.

**Apoptosis induction in primary multiple myeloma patient cells**

The ability of SAR650984 to induce apoptosis without the addition of external cross-linking agent was also tested in primary cells isolated from bone marrow aspirates of 7 patients with multiple myeloma. SAR650984 noticeably increased the percentages of Annexin V-positive cells over
background levels in all multiple myeloma samples tested with a mean increase of 25% Annexin V-positive cells (Fig. 3F).

**Enzymatic activity**

Inhibition of the ADP ribosyl-cyclase enzymatic activity of human CD38 by SAR650984 and other anti-CD38 antibodies was evaluated in vitro. SAR650984 inhibited the enzymatic function of 5 nmol/L recombinant CD38 almost completely at concentrations of 200 and 20 nmol/L with partial inhibition at 2 nmol/L concentration (Fig. 4A). A human IgG1 isotype control antibody had no measurable inhibitory effect in these experiments. Other anti-CD38 antibodies tested, Ab005 (a surrogate antibody for daratumumab), chHB7, huAT13/5, and chOKT10, resulted in much lower or no inhibitory effect (Fig. 4B).

**3D structure of the huCD38/SAR650984-Fab complex**

Mapping of the epitope and identification of the paratope were achieved by determining the crystal structure of soluble human CD38 (huCD38) in complex with the Fab fragment from SAR650984 at 1.53 Å resolution (PDB ID code: 4 CMH; Fig. 4C). Residues that are part of the huCD38 epitope bound by SAR650984-Fab are highlighted in Fig. 4D and notably include a continuous segment from Met110 to Cys119. Mutations introduced to silence the four glycosylation sites of CD38 are not part of the huCD38/SAR650984-Fab interface.

A close-up view of the epitope shows that the interface between huCD38 and SAR650984-Fab involves only part of the residues in the CDR loops (Fig. 4E). Heavy chain CDR Loop H3 protrudes out of the structure of SAR650984-Fab and is particularly critical for complex stabilization, whereas Loop H1, H2, L1, L2, and L3 are located at the periphery of the interface. Four salt-bridges form the interactions between H1 and H2 with Arg194 and Lys111 of huCD38 (Supplementary Fig. S2). Binding of SAR650984-Fab induces local conformational changes in the huCD38 structure. The most significant conformational change affects the segment Gln115-Thr116-Val117 of huCD38 that is shifted by approximately 2.5 Å toward the light chain, creating enough space to accommodate the H3 loop of SAR650984-Fab (Fig. 4E). However, the configuration of key residues involved in the ADP-ribosyl cyclase activity of CD38 is maintained and the catalytic site remains accessible (Fig. 4F), suggesting that SAR650984 is likely an allosteric antagonist.
In vivo activity against lymphoma and leukemia models

We evaluated the in vivo efficacy of SAR650984 in comparison with established lymphoma treatments such as rituximab and chemotherapy. SAR650984 showed similar antitumor activity as rituximab in a disseminated xenograft model established from CD20+ CD38+ Daudi lymphoma cells (Fig. 5A). Treatment with 40 mg/kg SAR650984 or rituximab twice weekly for 3 weeks markedly increased survival with a median increase in lifespan (%ILS) of 68% for SAR650984 and 52% for rituximab as compared with untreated control animals. SAR650984 was also highly efficacious in a disseminated NALM-6 B-ALL xenograft model, with a median%ILS of >200% at doses of ≥2.5 mg/kg (Fig. 5B). In a subcutaneous xenograft model derived from SU-DHL-8, a diffuse large B-cell lymphoma cell line, SAR650984 was active at all doses tested with T/C values of 8%, 14%, 14%, or 26% at the 40, 20, 10, or 5 mg/kg dose, respectively (Fig. 5C). No significant weight loss was observed as a result of SAR650984 treatment in any of these studies. CPA, an established lymphoma treatment component, was inactive at the 56 mg/kg dose level, active at 145 and 90 mg/kg (T/C values of 8% or 10%, and 12%, respectively (Fig. 6A). Bortezomib treatment at 0.7 or 0.4 mg/kg administered twice weekly for 2 weeks was inactive, whereas higher doses of 1.2 or 1.9 mg/kg were toxic.

Similarly, in a study with established NCI-H929 tumors, SAR650984 treatment was well tolerated and highly active at 40, 20, and 10 mg/kg × 6 with 10 of 10 tumor-free survivors and at 5 mg/kg × 6 with 9 of 10 tumor-free survivors at study end (Fig. 6B). Bortezomib administered twice weekly for 2 weeks was highly active at 0.6 mg/kg (T/C 7.8%; 4/10 tumor-free survivors) and at 1 mg/kg (10/10 tumor-free survivors). A higher bortezomib dose of 1.6 mg/kg was toxic, whereas a dose of 0.4 mg/kg was inactive.

Discussion

The introduction of therapeutic monoclonal anti-CD20 antibodies, such as rituximab, ofatumumab, and very recently obinutuzumab, is improving outcomes for patients with B-cell malignancies, although unmet medical need remains. It would be desirable to develop antibody therapeutics for other hematologic diseases, in particular...
multiple myeloma, that could also combine high efficacy with low systemic toxicity. Our goal was to build upon the success story of CD20 antibody therapy by developing a novel multifunctional antibody directed against a different target with expanded utility in a range of hematologic malignancies. Here, we describe the generation and characterization of SAR650984, a CD38-targeting antibody with a unique combination of antitumor activities.

The ability of SAR650984 to induce apoptosis in vitro was superior to rituximab in B-cell lymphoma cell lines with similar CD38 and CD20 expression, with potent activity even in the absence of cross-linking agents. This type of enhanced proapoptotic activity has been described for type II anti-CD20 antibodies such as tositumomab or obinutuzumab (37). In addition, SAR650984 induced apoptosis in multiple myeloma and T-ALL cell lines, which are typically CD20−, as well as a CD20− DLBCL cell line. Similarly to rituximab, SAR650984 mediated ADCC and ADCP effector activities with potent ADCC activity seen against cell lines derived from diverse CD38+ malignancies. Unlike type II anti-CD20 antibodies, SAR650984 also induced CDC in lymphoma cell lines with activity comparable with rituximab. SAR650984 demonstrated potent in vivo antitumor activities similar to rituximab in both disseminated and subcutaneous CD20+ CD38+ lymphoma models. Against DLBCL, SU-DHL-8 tumors SAR650984 activity compared favorably with CPA, a component of the standard treatment regimen CHOP, whose in vivo activity was limited by toxicity. In this model, SAR650984 also induced cleaved caspase-7, a marker of apoptotic cell death. Notably, SAR650984 was active against Molp-8 and NCI-H929 multiple myeloma xenograft tumors, whereas bortezomib, an agent commonly used in multiple myeloma treatment, was only active against NCI-H929 tumors.

Figure 4. CD38 enzymatic activity and 3D-structure of the huCD38/SAR650984-Fab complex. A, inhibition of CD38 enzymatic activity by SAR650984 measured in vitro by the production of cyclic GDP-ribose (cGDPR) from NGD++. B, inhibition of CD38 enzymatic activity at 90 minutes in the presence of 20 nmol/L of various anti-CD38 antibodies. C, overall structure of the complex in surface and ribbon representation with SAR650984-Fab heavy chains (yellow), light chains (green), and human CD38 (gray). D, amino-acid sequence of the R45-I300 huCD38 extracellular domain with SAR650984-Fab epitope residues in blue, mutations introduced to silence the four glycosylation sites of CD38 in light gray, CD38 active site residues in red. Epitope residues were defined as residues which contain atoms within 4Å from any atom of the SAR650984-Fab CDRs. E, detailed view of the epitope highlighting the contributions of loops H3 (yellow) and L1, L2, and L3 (green). F, overlay of CD38/SAR650984-Fab on free CD38 (PDB 2EF1, red), CD38 in complex with GTP (PDB 3DZH, magenta), and with NAD (PDB 2I65, cyan). Essential residues of CD38 involved in the enzymatic activity are shown in stick representation.
Several anti-CD38 antibodies with various functional properties have been identified previously. Although some of these can mediate in vitro killing of CD38+ cell lines via ADCC and/or CDC effector function, their direct impact on cell proliferation or apoptosis remains unclear (10, 22–24). For example, the agonistic antibody IB4 was reported to prevent apoptosis or induce proliferation in some contexts (10, 38), and induce apoptosis in another (9). The more recently developed antibody daratumumab has been shown to mediate ADCC as well as ADCP but to induce apoptosis only in the presence of stromal cells or cross-linking agents (28, 39). It was selected on the basis of its CDC activity, which may be linked to its unique epitope. Another recent addition, MOR202 primarily possesses ADCC activity with CDC and ADCP also being observed with no reported intrinsic proapoptotic activity (31, 32).

Analysis of the 3D structure of SAR650984-Fab with human CD38 revealed that SAR650984 binds to a discontinuous epitope which includes amino acids located opposite to the catalytic site of CD38. Although significant conformational changes are observed in CD38 upon binding by SAR650984, the overall configuration of key residues involved in the CD38 enzymatic activity and access to the catalytic site appear conserved (40–42). Nevertheless, SAR650984 strongly inhibits CD38 enzymatic activity suggesting that SAR650984 is an allosteric rather than an orthosteric antagonist of CD38. This is different from HB7, an antibody that does not compete with SAR650984 (Supplementary Fig. S3), binds at a different location in the C-terminal portion of the CD38 extracellular domain (Supplementary Fig. S4), and does not inhibit CD38 enzymatic activity (Fig. 4B). The SAR650984 binding mode appears unique as other anti-CD38 antibodies tested here or described elsewhere show no or much less potent inhibition of the enzymatic activity.

CD38 enzymatic activities produce nucleotide-metabolites including cADPR, which induce Ca2+ mobilization and signaling (7, 8, 43). However, the physiologic role of CD38 is still unknown, as functional studies have mainly used cell lines ectopically overexpressing CD38 and anti-CD38 antibodies, which are nonphysiologic ligands (44, 45). Therefore, the exact interplay between enzymatic activity, receptor function and consequences on signaling pathways and cellular response remains to be further documented. As a consequence, the physiologic impact of SAR650984 inhibition of CD38 enzymatic activity remains to be deciphered and how the functional differences observed between various anti-CD38 antibodies affect their therapeutic utility requires further investigation. The contribution of distinct mechanisms of action of SAR650984 to clinical efficacy may also differ depending on the type of hematologic malignancy, tumor biology, and tumor microenvironment.
antibody could offer the prospect of a highly effective therapy in multiple myeloma that might also be used readily in combination with other agents to improve clinical outcomes. On the basis of the results described here, SAR650984 has shown potent in vitro and in vivo activity against diverse CD38+ lymphoma, leukemia as well as multiple myeloma-derived cell line models and can induce apoptosis in primary multiple myeloma cells. Therefore, it presents an exciting opportunity for a novel antibody therapeutic in CD38+ hematologic malignancies and is currently in clinical testing in patients with multiple myeloma with early signs of efficacy (48).

**Disclosure of Potential Conflicts of Interest**

T. Chitinden holds ownership interest (including patents) in Immunogen. No potential conflicts of interest were disclosed by the other authors.

**Authors' Contributions**

Conception and design: M.-C. Wetzel, V.S. Goldmacher, C. Lahoute, C. Dumontet, P. Lejeune, P.U. Park, V. Blanc

Development of methodology: M.-C. Wetzel, Q. Zhou-Liu, P. Ferrari, P.U. Park

Acquisition of data (provided animals, acquired and managed patients, provided facilities, etc.): J. Deckert, M.-C. Wetzel, I.M. Bartle, A. Skaletskaya, F. Vallée, S. Pouzieux, C. Dumontet, A. Plesa, M. Chiron, P.U. Park

Analysis and interpretation of data (e.g., statistical analysis, biostatistics, computational analysis): J. Deckert, I.M. Bartle, P. Vallée, C. Dumontet, A. Plesa, M. Chiron, P. Lejeune, T. Chitinden, P.U. Park, V. Blanc

Writing, review, and/or revision of the manuscript: J. Deckert, M.-C. Wetzel, F. Vallée, Q. Zhou-Liu, C. Dumontet, M. Chiron, P. Lejeune, T. Chitinden, P.U. Park, V. Blanc

Administrative, technical, or material support (i.e., reporting or organizing data, constructing databases): Q. Zhou-Liu, P.U. Park

Study supervision: M.-C. Wetzel, P. Lejeune, T. Chitinden, P.U. Park

**Acknowledgments**

The authors thank Daniel Tavares, Michele Mayo, Hélène Bastien, Josiane Le Parc, François Michoux, Anne Pommerey, Dominique Quatteronot, Florence Attenot, and Catherine Geslin for technical support, Ti Cai for critical reading of the manuscript, and Walter Blätter, Thierry Hercend, Michel Streuli, and John Lambert for guidance and helpful discussions.
