ABSTRACT

Loss of expression of HLA class I antigens has been demonstrated in a wide variety of tumors and is considered to be one of the mechanisms whereby tumors escape T-cell surveillance. Genomic DNA of MHC class I/II molecules in seven lung cancer cell lines was investigated and compared with that in peripheral blood mononuclear cells. In three cell lines, OU-LC-A1, OU-LC-A2, and OU-LC-AS1, a loss of HLA haplotype was observed. Aberrations of HLA class I/II in tumor cell lines should be considered when MHC-restricted phenomena in vitro models are assessed and clinical use of tumor vaccination in vivo is considered.

INTRODUCTION

HLA class I molecules are transmembrane glycoproteins that consist of two polypeptide chains. The class I heavy chains are encoded by three principal genes (HLA-A, B, and C) within the HLA region of chromosome 6. The products of these genes are associated at the cell surface with a nonpolymorphic light chain, β2-microglobulin, and a cell-derived peptide to form a stable complex. Loss of expression of HLA class I antigens has been demonstrated in a wide variety of tumors. This may represent a mechanism whereby tumors escape T-cell surveillance (1–5).

Lung cancer represents the most frequent cause of cancer death among men world-wide, with an increasing overall incidence. The overall survival of lung cancer still remains <10%. Especially, advanced non-small cell lung cancer has an extremely poor prognosis because it is resistant to currently available chemotherapy and radiotherapy regimens (6). Therefore, development of specific immunotherapy using tumor-specific CTLs or tumor antigens is important for improving treatment modalities.

In this study, we investigated MHC class I/II molecules on seven newly established non-small cell lung cancer cell lines using PCR of genomic DNA.

MATERIALS AND METHODS

Cell Lines. Seven lung cancer cell lines were newly established in our laboratory. One cell line, OU-LC-AS1, was obtained and established from supravacular lymph node metastasis of a male with adenosquamous carcinoma of the lung. Five cell lines, OU-LC-A1, OU-LC-KI, OU-LC-A2, OU-LC-A3, and OU-LC-A4, were established from pleural effusion of males with adenocarcinoma of the lung. EBC-2 was established from pericardial effusion of males with squamous cell lung cancer. The cells were cultured in RPMI 1640 supplemented with 10% heat-inactivated fetal bovine serum.

DNA Samples. Genomic DNAs were prepared by the guanidine thiocyanate buffer [4 M guanidine thiocyanate, 25 mM sodium citrate (pH 7.0), 0.5% sodium N-lauroylsarcosinate, and 1% mercaptoethanol] lysis and phenol-chloroform extraction. First, leukocytes or cultured cells were mixed with guanidine thiocyanate buffer. After the solution was extracted twice with phenol and chloroform/isoamyl alcohol (29:1), DNA was precipitated with ethanol and suspended in 100 ng/μl in 10 mM Tris-HCl-1 mM EDTA buffer.

HLA-A, -B, -C, -DR, and -DQ Locus-specific PCR. Genomic DNA from each lung cancer cell lines or autologous PBMCs was typed for HLA-A using the PCR-RFLP and PCR-sequence-specific primer method described previously (7), for HLA-B using the PCR-sequence-specific oligonucleotide probes method described previously (8), for HLA-C using the PCR-sequence-specific primer method described previously (9), and for HLA-DQ and -DR using the PCR-RFLP method described previously (10–12).

HLA Class I/II Serological Typing of Alleles. T lymphocytes were prepared by Ficoll-Hypaque centrifugation followed by nylon-wool separation. Serological HLA class I/II typing of the T cell-enriched preparations was performed by a standard two-stage complement-dependent microcytotoxicity test using at least three monospecific alloantisera for the definition of each antigen (13).

2 The abbreviation used is: PBMC, peripheral blood mononuclear cell.
Loss of HLA Haplotype in Lung Cancer

RESULTS

Loss of HLA Haplotype in Non-Small Cell Lung Cancer Cell Lines. Table 1 shows a summary of HLA-class I/II typing of PBMCs and lung cancer cell lines from seven patients. Typing of PBMCs from OU-LC-AS1 was performed by PCR of the genomic DNA. Typing of PBMCs from other patients was performed by microcytotoxicity assay. HLA antigens from both alleles were detected in PBMCs from all seven patients. MHC class I and II genes in the lung cancer cell lines derived from those patients were investigated by PCR of the genomic DNA. A haplotype loss was observed in the three cell lines, OU-LC-AS1 (A24, 1.1, B51, 62, Cw*0102, *0303, DR4, *0301, DQ*0402), OU-LC-A2 (A26, 2, B51, 62, Cw*0102, *0303, DR4, *0301, DQ*0402), and OU-LC-KI (A2, B39, 51, Cw*0102, *0303, DR4, *0301, DQ*0402).

Loss of HLA Haplotype in OU-LC-AS1 Cells. Fig. 1 shows OU-LC-AS1 as an example. As shown in Fig. 1, a and b, a 262-bp fragment from exon 2 and a 294-bp fragment from exon 3 were amplified from both the PBMCs and the tumor cell line by A1*10101-specific primers (7). However, a 202-bp fragment from exon 2 and a 284-bp fragment from exon 3 were amplified from the PBMCs but not from the tumor cell line by A1*2402-specific primers. As shown in Fig. 1, c and d, 263-bp fragments were amplified from both the tumor cell line and the PBMCs by DR4-specific primers. In contrast, 266-bp fragments were amplified from the PBMCs but not from the tumor cell line by DR52-associated group-specific primers (12). Similar results were observed in HLA-B, -C, and -DQ allele group-specific PCR. These findings indicated that HLA-A*2402, B*1511, Cw*0303, DR14, and DQ*0531 genes are deleted in OU-LC-AS1 cells.

DISCUSSION

In this study, we showed that the allelic loss was caused by a deletion of a complete HLA haplotype in a high frequency (42.7%) in newly established lung cancer lines.
ies are necessary to determine their real prevalence and significance in human cancers.
