ABOUT THE COVER

Transmission electron micrograph shows 100 nm lipid vesicles that contain a highly concentrated complex of arsenic trioxide (> 270 mmol/L). This nanoparticulate formulation (termed “nanobin”) markedly improves the pharmacokinetics of the cytotoxic agent, resulting in enhanced antitumor efficacy in a murine model of breast cancer. Nanobin encapsulation of arsenic trioxide may increase its therapeutic utility in breast cancer and potentially other solid tumors. For further details, please see the article by Ahn and colleagues on page 3607 of this issue.
